

## Curl of a Vector

Consider a vector  $\mathbf{A}$  (we use **boldface** to denote a vector) with rectangular coordinates  $A_x$ ,  $A_y$ , and  $A_z$ . We can write  $\mathbf{A}$  as follows:

$$\mathbf{A} = A_x\mathbf{i} + A_y\mathbf{j} + A_z\mathbf{k}$$

where  $\mathbf{i}$  is a unit vector in the x direction,  $\mathbf{j}$  is a unit vector in the y direction, and  $\mathbf{k}$  is a unit vector in the z direction.

Using  $\nabla = \mathbf{i} \partial/\partial x + \mathbf{j} \partial/\partial y + \mathbf{k} \partial/\partial z$ , we define the *curl* of  $\mathbf{A}$ , written  $\nabla \times \mathbf{A}$  (“del cross A”) or **curl**  $\mathbf{A}$ , as follows:

$$\nabla \times \mathbf{A} = (\partial A_z/\partial y - \partial A_y/\partial z) \mathbf{i} - (\partial A_z/\partial x - \partial A_x/\partial z) \mathbf{j} + (\partial A_y/\partial x - \partial A_x/\partial y) \mathbf{k} \quad (1)$$

(For a quick review of partial derivatives, see <http://www.math.wisc.edu/~CONRAD/s08/partials.pdf>)

This is an ugly formula, so it is often written as a determinant:

$$\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ A_x & A_y & A_z \end{vmatrix}$$

(For a quick review of how to calculate determinants, see <http://www.ucl.ac.uk/mathematics/geomath/level2/mat/mat121.html>)

Notice that the curl is a *vector*. (It can be thought of as a cross product between the del operator – the  $\nabla$  – and the vector  $\mathbf{A}$ , but understanding that point is not essential to success here.)

The following websites may also be helpful:

<http://hyperphysics.phy-astr.gsu.edu/hbase/vvec.html>

**Simple EXAMPLE:**

Suppose  $\mathbf{A} = 3\mathbf{i} + 5\mathbf{j} + 7\mathbf{k}$ . This is a nice, simple, constant vector. Since all the components are constants, all the partial derivatives of the components are zero.

$$\nabla \times \mathbf{A} = 0$$

**More Complicated EXAMPLE:**

Suppose  $\mathbf{A} = 3x^2\mathbf{i} + 5xyz\mathbf{j}$ . Calculate **curl A**.

Before we start the formula, notice that in this example,  $A_z = 0$ , so several of the terms drop out.

$$\begin{aligned}\text{curl } \mathbf{A} &= (\partial A_z / \partial y - \partial A_y / \partial z) \mathbf{i} - (\partial A_z / \partial x - \partial A_x / \partial z) \mathbf{j} + (\partial A_y / \partial x - \partial A_x / \partial y) \mathbf{k} \\ &= (\partial / \partial y(0) - \partial / \partial z(5xyz)) \mathbf{i} - (\partial / \partial x(0) - \partial / \partial z(3x^2)) \mathbf{j} + (\partial / \partial x(5xyz) - \partial / \partial y(3x^2)) \mathbf{k} \\ &= -5xy \mathbf{i} + 5yz \mathbf{k}\end{aligned}$$

If you want to know the value of the curl at any point  $(x, y, z)$ , you just substitute the values of  $x$ ,  $y$ , and  $z$  into the curl formula.

To find the curl of the function above at the point  $x = 4$ ,  $y = 6$ ,  $z = 9$ , substitute those values into the curl formula for that function:

$$\text{curl } \mathbf{A} = \nabla \times \mathbf{A} = -5xy \mathbf{i} + 5yz \mathbf{k} = -5(4)(6) \mathbf{i} + 5(6)(9) \mathbf{k} = -120 \mathbf{i} + 270 \mathbf{k}$$

**Interpretation**

The curl represents how much a vector field “swirls” around a point, and indicates the direction of the “swirl.”

For a nice concise discussion of the physical interpretation of curl, see
