# Vector Addition

Vectors can be described by specifying either their magnitude and direction (polar coordinates) or their x and y components (rectangular, or Cartesian, coordinates). Consider a vector **A** (we use **boldface** to denote a vector) that has a length (or magnitude) A and makes an angle θ with the x-axis. The rectangular coordinates of **A** obey these formulae:

$$A_x = A \cos\theta \quad (1)$$
$$A_y = A \sin\theta \quad (2)$$

$$\text{Magnitude of } \mathbf{A} = |\mathbf{A}| = A = \sqrt{(A_x{}^2 + A_y{}^2)} \quad (3)$$

$$\text{Direction of } \mathbf{A} = \theta = \tan^{-1}(A_y/A_x) \quad (4)$$

Vectors are not added in the same way as ordinary numbers. Vector addition can be done in two ways: *graphically* or *analytically*. Each method involves a specific procedure that must be followed.

For ***Graphical Addition***, please review the applets listed below. It is necessary to use graph paper and a protractor to ensure that vectors are drawn to scale and at appropriate angles.

For ***Analytical Addition***, use the following rule:

*"The component of the sum equals the sum of the components. "*

That is, if **C** = **A** + **B**, then

$$C_x = A_x + B_x \quad \text{and} \quad C_y = A_y + B_y \quad (5)$$

The magnitude and direction of **C** are then defined as follows:

$$\text{Magnitude of } \mathbf{C} = |\mathbf{C}| = C = \sqrt{(C_x{}^2 + C_y{}^2)} \quad (6)$$

$$\text{Direction of } \mathbf{C} = \tan^{-1}(C_y/C_x) \quad (7)$$

**<u>EXAMPLE</u>:**

Suppose **A** = 3**i** + 5**j** and **B** = 4**i** – 2**j**. If **C** = **A** + **B**, determine the magnitude and direction of **C**.

**STEP 1: Identify the components of the individual vectors**

$A_x = 3$ $A_y = 5$ $B_x = 4$ $B_y = -2$

**STEP 2: Use equation (5) to compute the x and y components of the sum**

$C_x = A_x + B_x = 3 + 4 = 7$ $C_y = A_y + B_y = 5 + (-2) = 3$

**STEP 3: Use equation (6) to compute the magnitude of the sum**

Magnitude of $\mathbf{C} = \sqrt{(7^2 + 3^2)} = \sqrt{49 + 9} = \sqrt{58} = 7.62$

**STEP 4: Use equation (7) to compute the direction of the sum**

Direction of $\mathbf{C} = \tan^{-1}(3/7) = 23.2°$

Three or more vectors are added just as easily as two. When doing the addition analytically, just add up all the x components to find the total x component, and likewise for y. When doing the addition graphically, the only difference is that you add the vectors two at a time. In other words, add the first two and find the resultant; then add the third vector to this resultant to find a new resultant; then repeat the process until finished.

The *equilibrant* of a vector is the one that cancels it out – that is, the vector that when added to your original vector gives a resultant (sum) of zero. The equilibrant of any vector has the same magnitude but the opposite direction. Sometimes in vector algebra, you may see the equilibrant referred to as the *negative* of a vector. If you have a vector **A**, then the equilibrant may be written as –**A**.

So if **A** has components $A_x$ and $A_y$, then the equilibrant –**A** has components $-A_x$ and $-A_y$.
