

# Vector Dot Product

Consider a vector  $\mathbf{A}$  (we use **boldface** to denote a vector) with rectangular coordinates  $A_x$  and  $A_y$ . We can write  $\mathbf{A}$  as follows:

$$\mathbf{A} = A_x\mathbf{i} + A_y\mathbf{j}$$

where  $\mathbf{i}$  is a unit vector in the x direction and  $\mathbf{j}$  is a unit vector in the y direction.

If we have two vectors  $\mathbf{A}$  and  $\mathbf{B}$ , defined as above, then we define the *dot product* of  $\mathbf{A}$  and  $\mathbf{B}$ , written  $\mathbf{A} \cdot \mathbf{B}$  (read “A dot B”) as follows:

$$\mathbf{A} \cdot \mathbf{B} = A_xB_x + A_yB_y \quad (1)$$

Notice that the dot product is a *scalar*; it is the sum of one or more scalars. It may be referred to as the *scalar product*.

<http://www.falstad.com/dotproduct/>  
<http://betterexplained.com/articles/vector-calculus-understanding-the-dot-product/>

## Simple EXAMPLE:

Suppose  $\mathbf{A} = 3\mathbf{i} + 5\mathbf{j}$  and  $\mathbf{B} = 4\mathbf{i} - 2\mathbf{j}$

**STEP 1: Identify the components of each vector**

$$A_x = 3 \quad A_y = 5 \quad B_x = 4 \quad B_y = -2$$

**STEP 2: Use equation (1) to compute the dot product**

$$\mathbf{A} \cdot \mathbf{B} = A_xB_x + A_yB_y = (3)(4) + (5)(-2) = 12 - 10 = 2$$

## More Complicated EXAMPLE:

The rules are the same for three-dimensional vectors.

Suppose  $\mathbf{A} = 3\mathbf{i} + 5\mathbf{j} + 8\mathbf{k}$  and  $\mathbf{B} = 4\mathbf{i} - 2\mathbf{j} + \mathbf{k}$ . Compute  $\mathbf{A} \cdot \mathbf{B}$ .

**STEP 1: Identify the components of each vector**

$$A_x = 3 \quad A_y = 5 \quad A_z = 8 \quad B_x = 4 \quad B_y = -2 \quad B_z = 1$$

**STEP 2: Use equation (1) to compute the dot product**

$$\mathbf{A} \cdot \mathbf{B} = A_x B_x + A_y B_y + A_z B_z = (3)(4) + (5)(-2) + (8)(1) = 10$$

**Alternate Formula**

It happens that the dot product can also be calculated as follows:

$$\mathbf{A} \cdot \mathbf{B} = |\mathbf{A}| |\mathbf{B}| \cos \theta, \quad (2)$$

where  $|\mathbf{A}|$  is the magnitude of  $\mathbf{A}$ ,  $|\mathbf{B}|$  is the magnitude of  $\mathbf{B}$ , and  $\theta$  is the angle between them.

This formula may be helpful when you are given the magnitudes and angles to begin with.

**EXAMPLE:**

Suppose  $\mathbf{A}$  is a vector of magnitude 6 at an angle of  $60^\circ$ . Suppose  $\mathbf{B}$  is a vector of magnitude 4 at an angle of  $-25^\circ$ . Compute  $\mathbf{A} \cdot \mathbf{B}$ .

**STEP 1: Compute the angle  $\theta$  between the vectors**

$$\theta = 60^\circ - (-25^\circ) = 85^\circ$$

**STEP 2: Compute the cosine of the angle  $\theta$**

$$\cos \theta = \cos(85^\circ) \sim 0.0872 \text{ (rounding off)}$$

**STEP 3: Use equation (2) to compute the dot product**

$$\mathbf{A} \cdot \mathbf{B} = |\mathbf{A}| |\mathbf{B}| \cos \theta = (6)(4)(0.0872) \sim 2.09$$

**Interpretation**

The dot product of  $\mathbf{A}$  and  $\mathbf{B}$  can be thought of as the product of one vector times the component of the second that lies parallel to the first.

Note that  $\mathbf{A} \cdot \mathbf{B}$  ranges from 0 when  $\mathbf{A}$  and  $\mathbf{B}$  are perpendicular to  $|\mathbf{A}| |\mathbf{B}|$  when  $\mathbf{A}$  and  $\mathbf{B}$  are parallel.
